**CAS2K13, Annecy, France  
September, 2013**

# Overview

- Brief history of observations, climate modeling and Earth system modeling
- Prediction of 20<sup>th</sup>, 21<sup>st</sup> century and beyond climate change and its effect on society
- Four goals: advance the science, inform decision making, conduct assessments, and communicate and educate policymakers and the public
- What will be viable resolutions and complexity of future climate and Earth system models

# The Observational Story

# Historical CO<sub>2</sub> Levels

Lüthi et al.; Tans; IIASA<sup>2</sup>

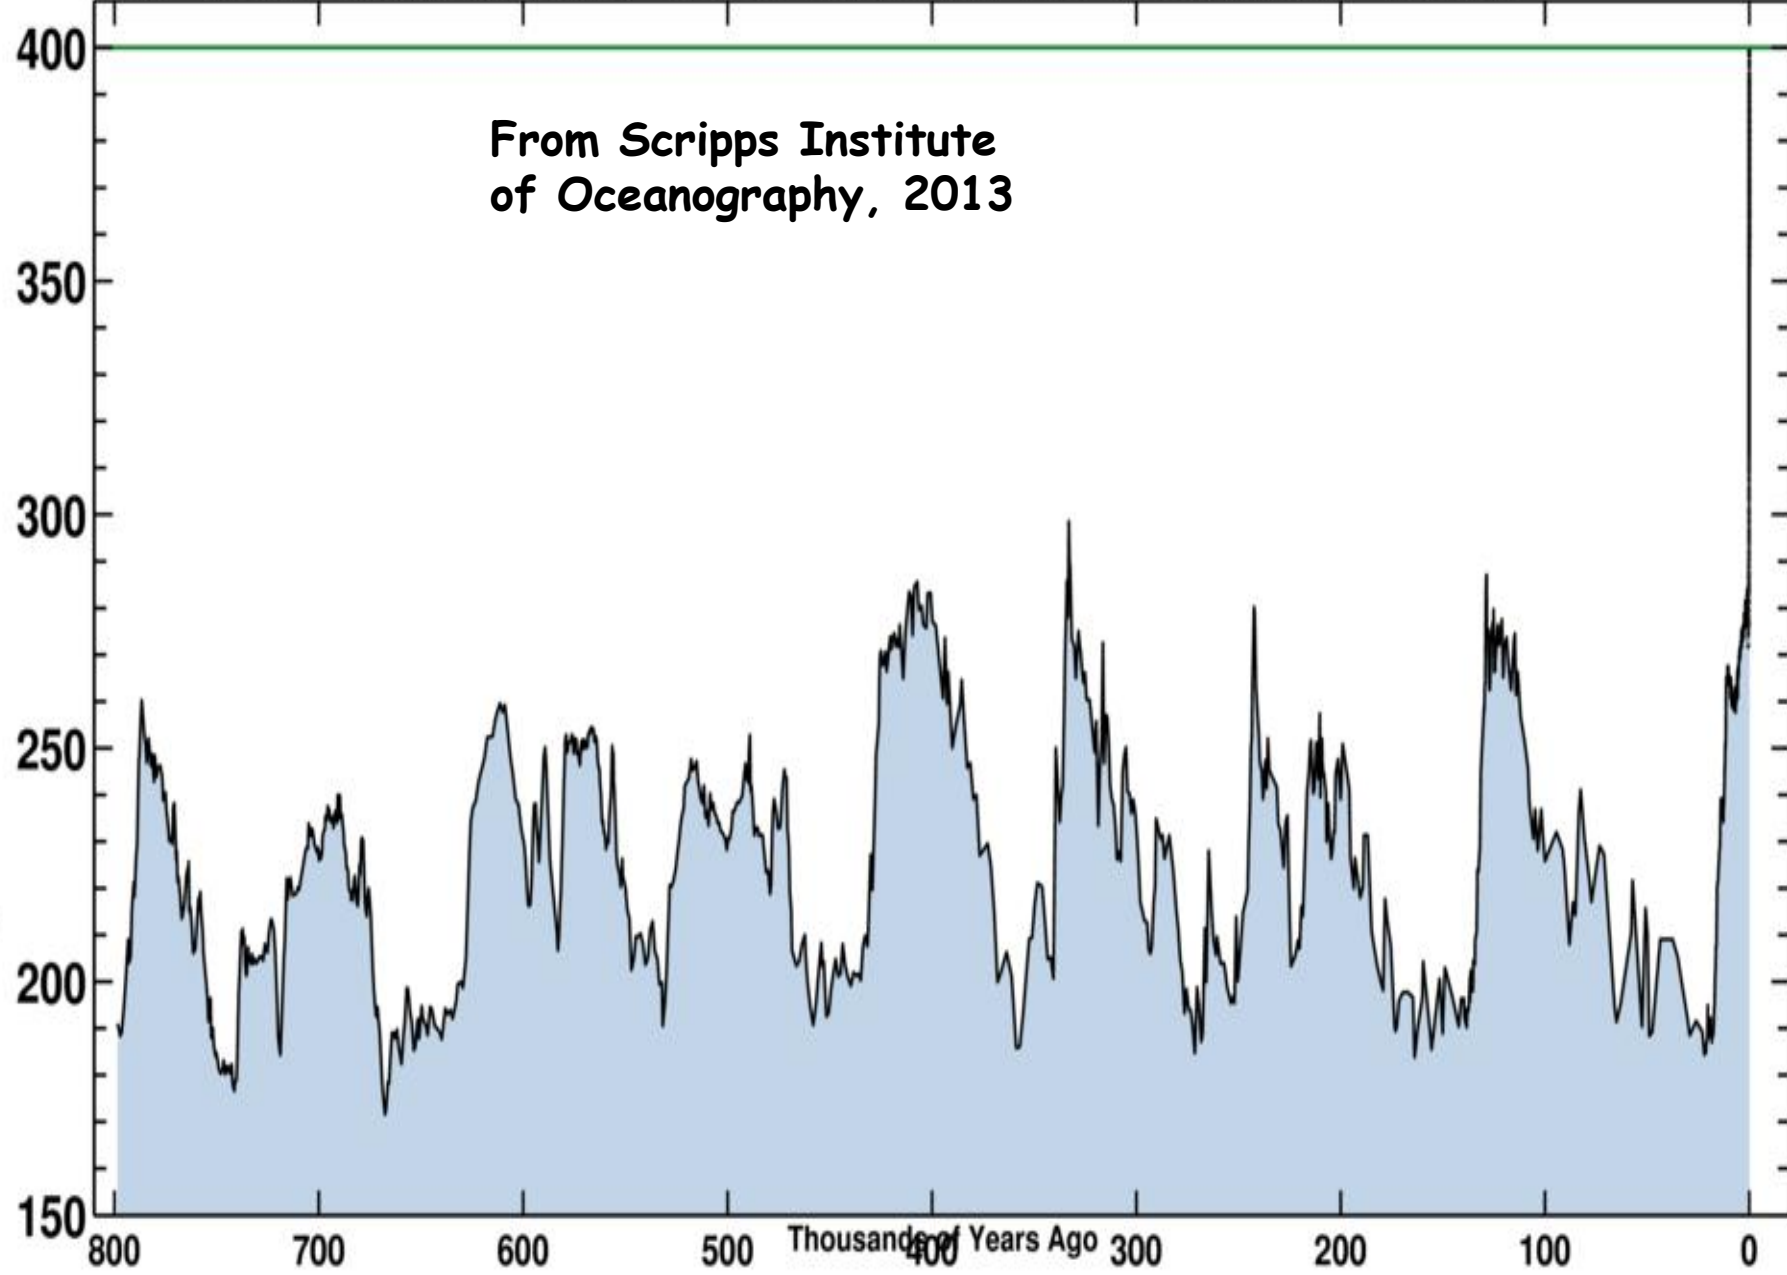

Analysis of air bubbles trapped in an Antarctic ice core extending back 800,000 years documents the Earth's changing carbon dioxide concentration. Over this long period, natural factors have caused the atmospheric carbon dioxide concentration to vary within a range of about 170 to 300 parts per million (ppm). Temperature-related data make clear that these variations have played a central role in determining the global climate. As a result of human activities, the present carbon dioxide concentration of about 385 ppm is about 30 percent above its highest level over at least the last 800,000 years. In the absence of strong control measures, emissions projected for this century would result in the carbon dioxide concentration increasing to a level that is roughly 2 to 3 times the highest level occurring over the glacial-interglacial era that spans the last 800,000 or more years.

Luthi et al: Tans

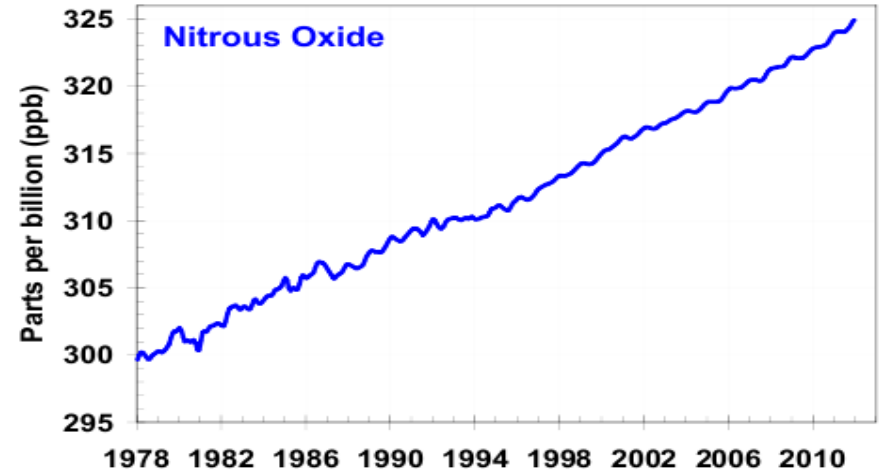

Ice-core data before 1958. Mauna Loa data after 1958.

# The Climate and Earth System Modeling Story

# Laws of Physics, Chemistry, and Biology

- Equations govern the dynamics of atmosphere, ocean, vegetation, and sea ice
- Equations put into a form that can be solved on modern computer systems
- Physical processes such as precipitation, radiation (solar and terrestrial), vegetation, boundary transfers of heat, momentum, and moisture at earth's surface are included
- Forcings: GHGs, Volcanic, Solar variations

A close-up photograph of a person's face, with a world map overlaying the features. The person has striking green eyes and is looking directly at the camera. The map is rendered in a vibrant, slightly blurred style, with blue oceans and various shades of green, yellow, and red for the continents. The overall composition is centered and fills most of the frame.

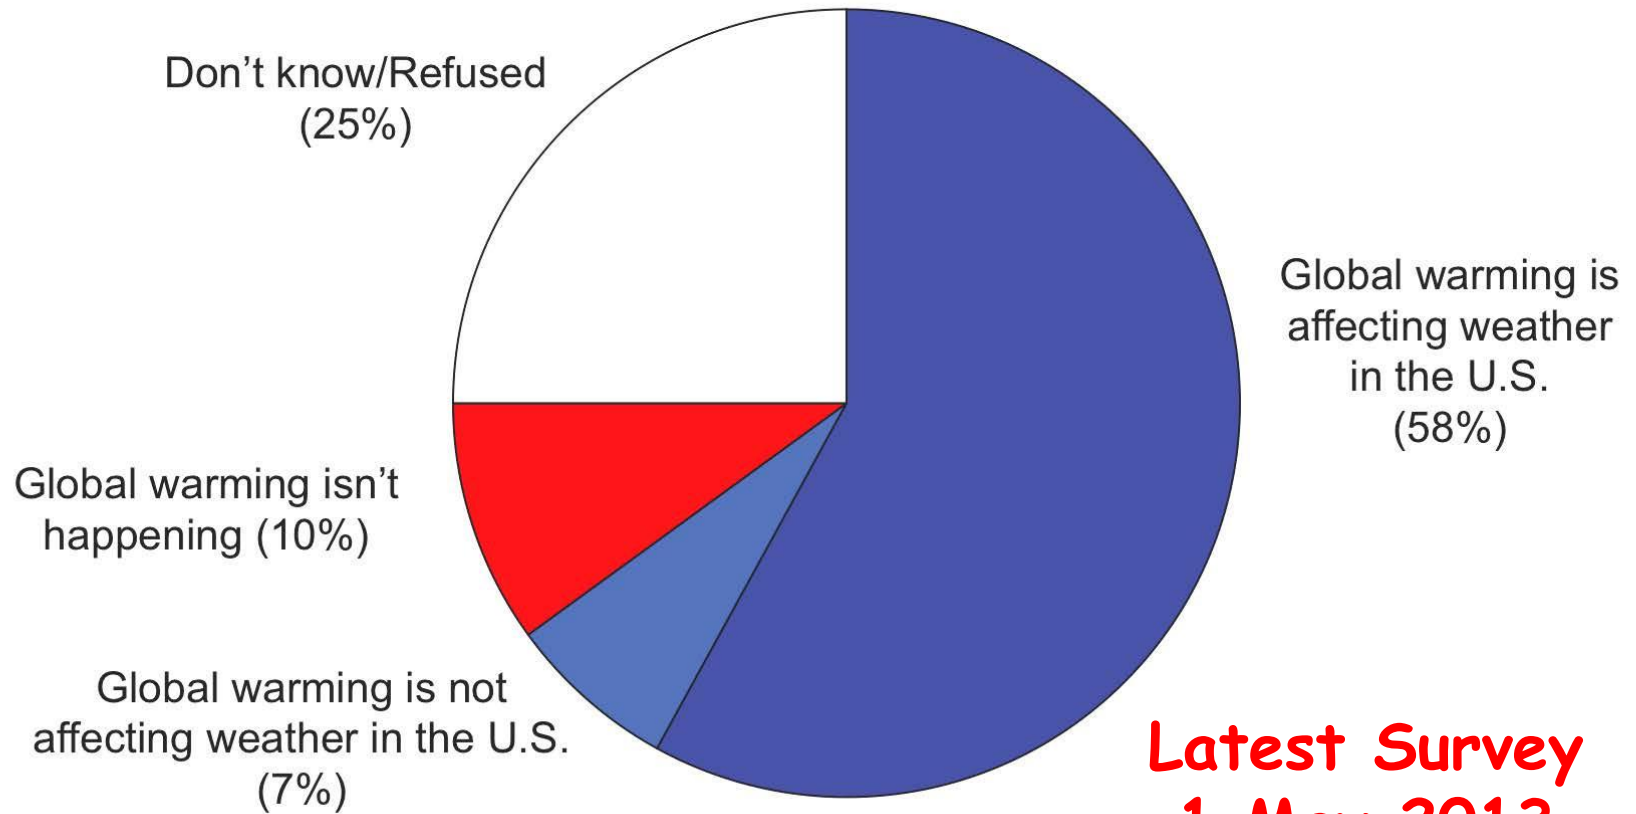

Climate and Earth System models have and continue to contribute to understanding and predicting the climate system. They allow the science community to determine objectively the possible impacts of climate change on food production, flooding, drought, sea level rise, and health as well as decision support. We need more emphasis on mitigation and adaptation. Higher resolution and more complete models will help.

# United States Research Goals for U.S. Global Change Research Program \$2.7B

- Goal 1. Advance science: Earth system understanding, science of adaptation and mitigation, observations, modeling, sharing information
- Goal 2. Inform decisions: Scientific basis to inform, adaptation and mitigation decisions
- Goal 3. Conduct sustained assessments: build capacity that improves Nation's ability to understand, anticipate, and respond
- Goal 4. Communicate and educate: Advance communication and educate the public, improve the understanding of global change, develop future scientific workforce

# Majority of Americans Say Global Warming Is Affecting Weather in the United States

■ A great deal   ■ Some   ■ Hardly any   ■ Don't know

From National Science Board S & E Indicators (2012)

# Where are we with respect to climate change?

- Mitigation versus adaptation...if we do nothing about greenhouse gas emissions then it is all adaptation. We need both.
- Models can provide vital information on both climate change and its impacts.
- Copenhagen, Cancun, Durban, and Doha climate change conferences suggest we have not solved the major policy aspects of future climate change.
- Where is the United States going on climate change policy? Future Earth?
